Fresh IEA report

Key recommendations

The government of Norway should:

- Stimulate further increases in oil and gas production from safe and environmentally sustainable operations and consider measures to prepare for a future with lower oil and gas revenues.
- Continue to support further harmonisation and integration within the Nordic electricity market, facilitate an increase in cross-border connections and demand-side measures to this end, and take measures to encourage market-based investments in low-carbon power generation.
- Develop a strategy to meet the 2030 and 2050 climate change targets.

Nord Stream 2

Financial Investors

Supplying natural gas to Europe

The Nord Stream 2 pipeline will transport natural gas into the European Union to enhance security of supply, support climate goals and strengthen the internal energy market.

The EU needs to import more gas

Domestic gas production is set to halve in the next two decades, as ageing assets are retired and hard-to-reach North Sea resources become uneconomic. The EU will need to import more gas and will need additional infrastructure to transport these imports. Nord Stream 2 together with other suppliers and supply routes (such as LNG) will meet these requirements – the share between them will be decided by the market.

Russia's geographic proximity, plentiful gas reserves and history of reliable supply make it a natural partner for a new gas transportation route that can enhance gas security.

Natural gas is a lower-carbon fuel

Demand for natural gas is predicted to continue. Natural gas is a lower-carbon fuel that can replace other fossil fuels in the energy mix and deliver a reliable output to complement intermittent renewable energy.

Today, the EU energy mix is still heavily reliant on coal, which produces about twice as much CO₂ as natural gas, and oil, which has 25 percent higher emissions.

BALTIC PIPE: new gas transmission pipeline, connecting Norway, Denmark and Poland

“Baltic Pipe is a potential new gas pipeline that would provide Denmark and Poland with a direct access to Norway’s gas fields”

<https://en.energinet.dk/Infrastructure-Projects/Projektliste/BalticPipe>

PROJECT OF COMMON INTEREST

The Baltic Pipe project has been included on EU’s list of important infrastructure projects – so-called Projects of Common Interest (PCI) – which are deemed essential to the integration of the European energy networks. As a result, the project has been granted EU funds to perform a feasibility study. Find an abstract of the feasibility study [here](#).

[Learn more about PCI](#)

“WIN-WIN FOR BOTH DENMARK AND POLAND

A feasibility study has shown that both Denmark and Poland are poised to gain from Baltic Pipe:

In Denmark, the massive volumes of gas transported from Norway to Poland through Baltic Pipe would create optimal conditions for a significant drop in transport tariffs for the Danish gas transmission system, which in turn would benefit Danish consumers and businesses. At the same time, Denmark’s direct access to Norway’s gas fields would also improve Denmark’s security of supply and increase competition in the gas market.

Similarly to other Central and Eastern European countries, Poland is dependent on gas from Russia. Baltic Pipe, in conjunction with a newly constructed Polish receiving station for liquid gas (LNG), will give Poland and its neighbour’s access to alternative sources of supply which in turn would improve security of supply.

IMPORTANT EUROPEAN PROJECT

EU has included Baltic Pipe on its list of key infrastructure projects that are of common interest to Europe – also known as “PCI projects”. This is due to the essential role Baltic Pipe could play in contributing to the development of Europe’s internal market for gas, and the fortification of EU’s security of supply.” <https://en.energinet.dk/Infrastructure-Projects/Projektliste/BalticPipe>

Exploration History

Impact of Glaciations and Interglaciations extends far south of Barents Sea

The rest of the NCS was also covered by ice sheets during the last three glaciations, including Utsira High, so why is there HC leakage in one place and not the other?

Is it due to the thin or absent Paleogene and Neogene sections in places?

Or could there be more to it that we don't yet understand?

Exploration History

Can it really be that bad?

- Hekkingen Fm oil from Bjørnøya Basin migrated into Johan Castberg*
- Oil from Tromsø Basin in Filicudi?
- Possible oil shows in Pingvin well?

An overview map illustrating the main findings and reasons for failures in the Western Barents Sea.

The oil that has migrated into the Johan Castberg area appears to come from Bjørnøya Basin.

But which area does the Filicudi oil come from? From the south? And if so, which source rock is the primary source rock for the oil found in the discovery?

Summary on Evaporites and Carbonates

- Carboniferous and Permian carbonates and evaporites with seismic scale carbonate buildups are widely distributed in the southern Barents Sea, strongly controlled by Paleozoic structural architecture.
- Paleozoic grabens and structural lows with evaporites / salt have been inverted in Mesozoic(?), Paleogene and Neogene, forming traps.
- A working petroleum system is proven.
- Spectral Decomposition is an excellent tool for identifying geomorphologies in really old seismic data – imagine what you can do with new data...

CHALLENGES IN EASTERN BARENTS SEA

Challenges in the Eastern Barents Sea

Source Rocks

PRESENCE AND QUALITY OF SOURCE ROCK

Will it/they have expelled enough hydrocarbons to fill an 800 km² structure?

Challenges in the Eastern Barents Sea

Challenges in Western Barents Sea

Lithostratigraphy versus Chronostratigraphy

NPD lithostratigraphy published in 1988, based on earliest exploration wells in Barents Sea.

3 wells used for reference & type wells for entire post-Jurassic succession (7119/12-1, 7120/12-1 & 7121/5-1), drilled in Hammerfest Basin & Ringvassøy-Loppa Fault Complex.

No formalised subdivision of the Paleogene succession (Torsk Fm).

Application of Cretaceous lithostratigraphy is subtle, even in the type & reference wells.

Consistency with wells drilled in WBS is highly problematic in the absence of biostratigraphic data, which generates a circular argument and undermines the principle of lithostratigraphy.

Far more intra-formational variation than inter-formational differences.

Solution to the challenge: use a chronostratigraphic approach

- New erosion model based on observations from wells and seismic data →

new petroleum system model

Play fairway maps indicate:

- Low, moderate and high possibility for reservoir presence
- Hydrocarbon expulsion for a given source rock at the time of trap formation
- Retention risk is *not* included

Opportunities in Western Barents Sea

A viable oil play?

Play Fairway Map Example:

SUMMARY

SUMMARY

Main Challenges

- Main challenge for Eastern Barents Sea is presence and quality of source rock
- Main challenge for Central Barents Sea is migration and trap size
- Main challenge for Western Barents Sea is to drill the right wells to efficiently understand the migration history and plays better + tectonic uplift in north area

SUMMARY

Main Opportunities

- Main opportunity for Eastern Barents Sea is proving source rock + possible traps straddling Fedynsky High
- Main opportunity for Central Barents Sea will be included in the Prospect Database
- Main opportunity for Western Barents Sea: big traps and a viable oil plays
